NEW QUESTION: 2 The RSA Algorithm uses which mathematical concept as the basis of its encryption?**A.** 16-round ciphers**B.** PI (3.14159...)**C.** Geometry**D.** Two large prime numbers**Answer: D**
Explanation: Source: TIPTON, et. al, Official (ISC)2 Guide to the CISSP CBK, 2007 edition, page 254. And from the RSA web site, <http://www.rsa.com/rsalabs/node.asp?id=2214> : The RSA cryptosystem is a public-key cryptosystem that offers both encryption and digital signatures (authentication). Ronald

Rivest, Adi Shamir, and Leonard Adleman developed the RSA system in 1977 [RSA78]; RSA stands for the first letter in each of its inventors' lastnames. The RSA algorithm works as follows: take two large primes, p and q , and compute their product $n = pq$; n is called the modulus. Choose a number, e , less than n and relatively prime to $(p-1)(q-1)$, which means e and $(p-1)(q-1)$ have no common factors except 1. Find another number d such that $(ed - 1)$ is divisible by $(p-1)(q-1)$. The values e and d are called the public and private exponents, respectively. The public key is the pair (n, e) ; the private key is (n, d) . The factors p and q may be destroyed or kept with the private key. It is currently difficult to obtain the private key d from the public key (n, e) . However if one could factor n into p and q , then one could obtain the private key d . Thus the security of the RSA system is based on the assumption that factoring is difficult. The discovery of an easy method of factoring would "break" RSA (see Question 3.1.3 and Question 2.3.3). Here is how the RSA system can be used for encryption and digital signatures (in practice, the actual use is slightly different; see Questions 3.1.7 and 3.1.8):

Encryption Suppose Alice wants to send a message m to Bob. Alice creates the ciphertext c by exponentiating: $c = m^e \text{ mod } n$, where e and n are Bob's public key. She sends c to Bob. To decrypt, Bob also exponentiates: $m = c^d \text{ mod } n$; the relationship between e and d ensures that Bob correctly recovers m . Since only Bob knows d , only Bob can decrypt this message.

Digital Signature Suppose Alice wants to send a message m to Bob in such a way that Bob is assured the message is both authentic, has not been tampered with, and from Alice. Alice creates a digital signature s by exponentiating: $s = m^d \text{ mod } n$, where d and n are Alice's private key. She sends m and s to Bob. To verify the signature, Bob exponentiates and checks that the message m is recovered: $m = s^e \text{ mod } n$, where e and n are Alice's public key. Thus encryption and authentication take place without any sharing of private keys: each person uses only another's public key or their own private key. Anyone can send an encrypted message or verify a signed message, but only someone in possession of the correct private key can decrypt or sign a message.

NEW QUESTION: 3

Threat modeling's motto should be, "The earlier the better, but not too late and never ignore." Box 2: Static code

analysis Validation in the CI/CD begins before the developer commits his or her code. Static code analysis tools in the IDE provide the first line of defense to help ensure that security vulnerabilities are not introduced into the CI/CD process. Box 3: Penetration testing Once your code quality is verified, and the application is deployed to a lower environment like development or QA, the process should verify that there are not any security vulnerabilities in the running application. This can be accomplished by executing automated penetration test against the running application to scan it for vulnerabilities. References:
