NEW QUESTION: 1
A server administrator notes that a legacy application often stops running due to a memory error. When
reviewing the debugging logs, they notice code being run calling an internal process to exploit the
machine. Which of the following attacks does this describe?
A. Buffer overflow
B. Cross site scripting
C. Malicious add-on
D. Zero-day
Answer: A
Explanation:
Section: Threats and Vulnerabilities
Explanation/Reference:
Explanation:
This question describes a buffer overflow attack.
A buffer overflow occurs when a program or process tries to store more data in a buffer (temporary data
storage area) than it was intended to hold. Since buffers are created to contain a finite amount of data, the
extra information - which has to go somewhere - can overflow into adjacent buffers, corrupting or
overwriting the valid data held in them. Although it may occur accidentally through programming error,
buffer overflow is an increasingly common type of security attack on data integrity. In buffer overflow
attacks, the extra data may contain codes designed to trigger specific actions, in effect sending new
instructions to the attacked computer that could, for example, damage the user's files, change data, or
disclose confidential information. Buffer overflow attacks are said to have arisen because the C
programming language supplied the framework, and poor programming practices supplied the
vulnerability.
